Air Conditioning in Aircraft Cabins and the Associated Air Quality

Abstract

Passenger aircraft occasionally encounter a Cabin Air Contamination Event (CACE). When these events make themselves know with a distinct smell they are called Smell Events. When they are evident even by smoke (and smell), they are called Fume Events. The objectionable classical cabin air contamination from "bleed", "engine oil", "hydraulic fluid", and "deicing" accounts together for roughly 1/3 of the events. Oil has left traces on its way from the engine to the cabin interior: In bleed air ducts, air conditioning ducts, in recirculation filters, on cabin surfaces (wall panels, seats ...). Hydro carbon concentrations in the cabin can be calculated and agree with measurements. SAE has highlighted the risk of obtaining contaminated air from the engine compressor. It may preclude its use for transport aircraft, regardless of other good reasons. Nevertheless, aviation organizations like IATA claim that "Cabin air is as clean as a hospital operating theatre". Cabin air ventilation in passenger aircraft is done with outside air. At cruise altitude, ambient pressure is below cabin pressure. Hence, the outside air needs to be compressed before it is delivered into the cabin. The most economic system principle simply uses the air that is compressed in the engine compressor anyway and taps some of it off as "bleed air". The engine shaft is supported by lubricated bearings. They are sealed against the air in the compressor usually with labyrinth seals. Unfortunately, the jet engine seals leak oil by design in small quantities. The oil leaking into the compressor contains toxic additives. Furthermore, the oil includes toxic metal nanoparticles – normal debris from the engine. An alternative source for the compressed air is the Auxiliary Power Unit (APU). Like the aircraft's jet engine, it is a gas turbine, built much in the same way when it comes to bearings and seals. For this reason, also compressed air from the APU is potentially contaminated in much the same way. Compressed air from the engine is also used to pressurize the potable water. It has been observed that the potable water on board can also be contaminated. Fan air and bleed air ducts at the interface between engine and wing carry outside compressed air. The inside of the ducts shows differences. The brown stain in the bleed air duct appears to be engine oil residue. In comparison, the fan air duct is clean. This shows that oil leaves the compressor bearings. Ducting further downstream shows a black dry cover. The reason for the change in color seems to result from the different air temperatures: 400 °C at engine outlet and 200 °C further downstream behind the precooler. The water extractor is a part of the air conditioning pack. The inlet of the water extractor is covered with black oily residue, because the temperature is even lower at this point. The air conditioning air distribution ducts in the cabin are black inside from contaminated bleed air. New ducts are clean. Air duct are even clean inside at the end of the aircraft's life, in areas where they are used such that no bleed air flows through them. Flow limiters have been found in ducts of the air conditioning system that are clogged from engine oil. Also riser ducts feeding the cabin air outlets are black inside from engine oil residue.
Cleaning on top of the overhead bins brings to light dirt that is clearly more than dust. The black residue known from the ducts settles also on the bin surface. Deicing fluid and hydraulic fluid can find their way into the air conditioning system via the APU air intake. A fence and a deflector around the air intake cannot fully prevent contaminants from entering the APU. Traces of contamination tend to be visible on the lower part of the fuselage. Contaminants are carried by the air flow in flight, from the landing gear bay to the APU inlet. Hydraulic systems are never leak free. A hydraulic seal drain system tries to collect hydraulic fluid leaving the system with partial success. It is impossible to catch all leaking hydraulic fluid. If the containers of the seal drain system are not emptied they spill over. In old aircraft, surfaces in the landing gear bay are covered with a layer of hydraulic fluid. Dirt accumulates on the sticky surface. The hydraulic fluid is not confined to the inside of hydraulic bays, but continues its journey on the lower side of the fuselage towards the APU. Deicing fluid if applied in the winter to the aircraft and can leak from the tail into the APU inlet. Fuel and oil also leak down onto the airport surfaces. These fluids can be ingested by the engine from the ground and can enter the air conditioning system from there. Entropy is the law of nature that states that disorder always increases. This is the reason, why it is impossible to confine engine oil and hydraulic fluids to their (predominantly) closed aircraft systems. This is why engine oil with metal nanoparticles hydraulic fluids, and deicing fluids eventually go everywhere and finally into the human body. Filtration can help to avoid cabin air contamination. HEPA filters are in use with most passenger aircraft that work with recirculated air. Only HEPA carbon filters can also filter some of the Volatile Organic Compounds (VOCs). They are available for only some aircraft types and only lead to about 40% reduction of the concentration of VOCs in the cabin. Necessary would be to filter the incoming air from the engine compressor. Filter manufacturer Pall has worked on such a total air filtration option for the Airbus A320 for several years, but is so far not able to offer the new system. For this reason, we are left with a situation, where engines are longer and longer on the wing without the chance to replace engines seals that get worn out more the longer the engine is operated. This leads to an increasing number of CACEs. Airbus duct cleaning maintenance procedures after a CACE are ineffective. Aircraft released back into service over night after an (oil based) CACE are not cleaned as instructed by Airbus, because ducts cannot be removed from behind the panels in this short time, the inside of ducts is not accessible, and most of the deposit are firmly attached to the surface and cannot be removed. This situation leaves the passengers in a situation for which the degree of contamination is unknown but real. Strictly, the amount of oil in the cabin cannot be determined from the oil consumption of the engine. For legal benefit of the aviation industry, sensors are missing on board and deprive passengers and crew from data that could be used in court.

Introduction
**Definition: Fume Event**

In a fume event, the cabin and/or cockpit of an aircraft is filled with *fume*. Air contamination is due to fluids such as engine oil, hydraulic fluid or anti-icing fluid. A Fume Event includes a Smell Event. Note: Other reasons for fume in the cabin are possible. The term "fume event", however, is generally used as defined here. Definition adapted from (Wikipedia 2019)

**Definition: Smell Event**

A fume event without visible fume or smoke, but with a distinct *smell* usually described as "dirty socks" from the butyric acid originating from a decomposition of the esters that are the base stock of the synthetic jet engine oil.

**Definition: Cabin Air Contamination Event (CACE)**

In a Cabin Air Contamination Event (CACE) the air in the cabin and/or cockpit of an aircraft is contaminated. Sensation of the contamination can be from *vison* (fume/smoke), *olfaction* (smell/odor), a combination of typical *symptoms* experienced by several passengers and/or or crew or by related *measurements* of CO, CO2, ozon or other "harmful or hazardous concentrations of gases or vapours" (CS-25.831).

**2019-08-22: Hawaiian Airlines, A321neo**

Emergency Landing and Evacuation; Smoke on Board

#### Oakland to Honolulu, Flight HA47, A321neo, N218HA ()

**21:13:** Top of Descent: Smoke starts to fill cabin i.e. when thrust setting changed.

21:16: Pilots received a fire warning from the cargo compartment and declared an in-flight emergency.

21:36: Landing. After landing there was "no visible evidence of fire, no visible flames" said Snook. "We have since determined that a seal failed in the aircraft’s left engine" said Da Silva.

**Direct (emergency) venting with ram air** (independently of bleed air) is possible **below 10000 ft**, but was **not used**.

Introduction

Reasons for Cabin Air Contamination Events (CACEs)

Anderson (2019 and 2021) lists the reasons for cabin air contamination events.

Onboard Fumes/Smoke Reported by U.S. Airlines total 12452 events of different source. The objectionable classical cabin air contamination from "bleed", "engine oil", "hydraulic fluid", and "deicing" accounts together for roughly 1/3 of the events. Industry often quotes "oven" as the main reason, but it only accounts for 3.1%.
Introduction

How Often are Cabin Air Contamination Events (CACEs)?

According to Michaelis (2010) no (exact) figure can be given to the question of how many cabin air contamination events occur. Neither manufacturer, nor airline, union or government agency knows it. There is tremendous underreporting.

</tr>
</tbody>
</table>

Michaelis (2003) reports about a survey done with UK pilots flying Boeing 757 airplanes. Underreporting here was at about 4%. In other words, there were 25 times more cases than being reported.

5.6 events per 100000 flights can be estimated (Anderson 2019). This is more than one event in 20000 flights. If underreporting is considered with 10% (instead of 4%), we would need to expect one cabin air contamination event every 2000 flights.
How Do We Know about Oil in the Cabin?

Oil has left traces on its way from the engine to the cabin interior:
1. Oil traces in bleed air ducts
2. Oil traces in air conditioning ducts
3. Oil traces in recirculation filters
4. Oil traces on cabin surfaces (wall panels, seats, ...)
5. Hydro carbron concentrations in the cabin can be calculated and agree with measurements

Evidence collected in Scholz 2017 and Scholz 2019 summarized here:

\[
\frac{m_{oil,cab}}{V_{cab}} = \frac{\dot{m}_{oil} \cdot x_{bear,up} \cdot x_{seal}}{S_{eng} \cdot n_{eng} \cdot M_{CR} \cdot a(h_{CR}) \cdot \frac{P_{cab}}{P_{CR}} \cdot (\mu + 1)}
\]
Example Calculation Compared with Measurements

\[ \frac{m_{oil, cab}}{V_{cab}} = 17 \ \mu g/m^3 \]

with conservative estimate:
\[ x_{seal} = 1 \% \]

(EASA 2017a)
Introduction

Engineering Design Principles for Air Conditioning from SAE

SAE AIR 1168-7: Aerospace Pressurization System Design

“Compressor bleed from turbine engines is attractive because of the mechanical simplicity of the system.” However, “oil contamination ... can occur in using compressor bleed air from the main engines.” “Popular opinion regarding the risk of obtaining contaminated air from the engine may preclude its use for transport aircraft, regardless of other reasons.”
Nevertheless, it is claimed:

https://perma.cc/686X-X9AZ?type=image
Air Conditioning System
**Boundary Conditions**

- **Atmospheric conditions**
  - Oxygen content: 21%; independent of altitude.
  - Pressure: 22% of sea level pressure.
  - Temperature: -56 °C.

- **Aircraft is no submarine.**
  - Aircraft is open to the environment to draw air.
    - Outside ("fresh") air can be used, but needs to be compressed. This requires energy.
    - Compression delivers very high temperatures (based on thermodynamics).
    - Cooling is necessary
      1.) to get the temperature down to normal levels
      2.) to cool the cabin, because the cabin experiences net heating due many passengers, system inefficiencies converted into heat, ...
Air Conditioning System

Requirements

- Ventilation
  - "the ventilation system must be designed to provide a **sufficient amount** of uncontaminated air" "to provide each occupant with an airflow that contains at least **0.25 kg of fresh air** [outside air] **per minute**" CS-25.831(a) "i.e. 10 cubic feet per minute of air at 8000 feet pressure altitude and at a cabin temperature of 24 °C" AMC 25.831(a)(1)
  - "Where the air supply is supplemented by a **recirculating system**, it should be possible to stop the recirculating system and –
    a. Still maintain the fresh air supply prescribed, and
    b. Still achieve 1 [avoid contamination]." AMC 25.831(c)
  - "Each passenger and crew compartment must be ventilated ... to enable crewmembers to perform their duties **without undue discomfort or fatigue**." CS-25.831(a)
  - "Crew and passenger compartment air must be **free from harmful or hazardous concentrations of gases or vapours**." CS-25.831(b)
  - CO, CO2, ozone concentration limits are given, but not for other substances. This does not mean that other substances are allowed in any concentration (BFU 2014) "The BFU is of the opinion that a product [aircraft] which has received a type certificate by EASA should be designed in a way that neither crew nor passengers are harmed or become chronically ill." (BFU 2014)
Air Conditioning System

Requirements

- Temperature Control
  - Cabin air temperatures are not defined in CS-25.
  - Temperature control is done by ventilation with (in most cases) cold air.
  - Recirculation allows to use "more air" at temperatures "not as cold" as required with less air.
  - Hence, recirculation
    - allows a more even temperature distribution in the cabin,
    - avoids cold drafts near passengers and increases cabin comfort.
  - "More air" (than required) could also be obtained from outside, but ...
    - outside air needs to be compressed (to cabin pressure), which requires more energy.
    - recirculated air only needs to be pumped (against pressure losses in tubes); it saves energy.
  - Recirculated air spreads air among all passengers (unlike outside air), hence need of filtration.

- Pressure Control
  "provide a cabin pressure altitude of not more than 8000 ft" CS-25.841(a)

- Moisture Control
  No requirements

Requirements related to pressure and moisture control are not further detailed.

Lubrication and Sealing of Engine Bearings

Normal operation of engine seals:
1. The "drain" discharges oil.
2. The "dry cavity" contains oil.
3. Air and oil leak from bearings into the bleed air.

=> Engines leak small amounts of oil by design!

Based on Exxon 2017
Metal Particles
Engine Metals from the Oil into the Body

**Used Oil Analysis for Metal Particles**

- **Spectrometric Oil Analysis** Program (SOAP) is an analysis of metal particles in the oil.
- SOAP can be combined with oil filter inspection and magnetic chip detector inspection which identifies larger metal particles.
- A monitor program helps to identify the condition of the engine:
  - **Catastrophic** failure of mechanical parts usually generate larger metal particles that can be analysed in magnetic chip detectors.
  - **Slow progressing damage** to gears, bearings and spinning bearing races in the engine case is identified with SOAP. Wear particle size is between 1 µm and 5 µm.
  - **Normal wear** can produce even smaller particles (nano particles).
  - The most important wear metal in the evaluation is iron followed by chromium – both are present in bearings. If the engine case is titanium, increased titanium levels indicate a spinning bearing outer race.
  - Larger metal particles will stay in the engine.

**Metal micro and nano particles can leave the engine together with the oil into the cabin!**

Filtration Systems
Filtration Systems

Filter in the Recirculation Path

Pall offers Odour/VOC Removal Filters
• "The carbon adsorbent is effective at adsorbing volatile organic compounds (VOC). Test results have shown a removal efficiency of 65% ... 73% when challenged with TCPs in the gaseous phase." (Pall 2011)

Application of Carbon Filters
• HEPA-Carbon filters have been added to 33 A321 aircraft at Lufthansa Group so far. (Lufthansa 2017)
• These filters are located in the recirculation path of the cabin air.
Filtration Systems

Efficiency of Filter in the Recirculation Path

Example calculation:

- With a filtration rate, $x_{fil} = 0.7$ (Pall 2011) and a recirculation rate, $x_{re} = 0.5$ (A320) the filter in the recirculation path reduces the incoming concentration to 58.9%.

\[
\frac{x_{cont,cab}}{x_{cont,in}} = \frac{1 - x_{re}}{1 - (1 - x_{fil}) x_{re}}
\]

for $x_{fil} = 1$:

\[
\frac{x_{cont,cab}}{x_{cont,in}} = 1 - x_{re}
\]
Filtration Systems

Full *
Filtration
Option: 3b

*Filtration of cold air only. Hot trim air is not filtered. Filtration also in recirculation.
Maintenance
Engines Longer on Wing
Labyrinth-Seal Clearances Increase as Engines Age

"Labyrinth-seal clearances naturally increase as an engine ages. As this occurs – due to rubbing under vibration, gyroscopic torque, rough landings or any g-load factor, the engine air flow increases, resulting in even higher oil consumption" (Exxon 2016a) and hence leakage into the bleed air.

The figure shows increasing time to first shop visit of CFM56-7B engines. It follows:

During a period of 10 years (2004 to 2014) maintenance practice changed such that engines stay on the wing almost twice as long without shop visit and seal replacement.

Source: FDM TOW data, CFM56-7B
(AviationWeek 2016)
Maintenance

Cabin Air Ducts

Insufficient / Impossible Duct Cleaning

In the case of heavy contamination, this being assumed when there are visible traces of oil on the internal surface of the ducts, it is necessary to manually clean the affected ducts using rags and an appropriate degreasing agent.

(Airbus 2013)

Aircraft released back into service over night after an (oil based) CACE are not cleaned as instructed by Airbus, because

• ducts cannot be removed from behind the panels in this short time,
• the inside of ducts is not accessible,
• most of the deposit cannot be removed.
Entropy – Distribution by Law of Nature
Entropy – Distribution by Law of Nature

Contaminants Spread Everywhere

Gas spreads to fill space over time

Entropy (Disorder) Always Increases!

Pile of bricks dropped from a truck
Entropy is the law of nature by which ... 

• engine oil with metal nanoparticles 
• hydraulic fluid 
• deicing fluid 

goes everywhere and finally into the human body.
